

# Arrays

# Can we solve this problem?

- Consider the following program (input underlined):

How many days' temperatures? 7

Day 1's high temp: 45

Day 2's high temp: 44

Day 3's high temp: 39

Day 4's high temp: 48

Day 5's high temp: 37

Day 6's high temp: 46

Day 7's high temp: 53

Average temp = 44.6

4 days were above average.

# Why the problem is hard

- We need each input value twice:
  - to compute the average (a cumulative sum)
  - to count how many were above average
- We could read each value into a variable... but we:
  - don't know how many days are needed until the program runs
  - don't know how many variables to declare
- We need a way to declare many variables in one step.

# Arrays

- A programmer commonly needs to maintain a list of items.
- **Array**: is an ordered list of items of a given data type.
- **Element**: Each item in an array is called an **element**.
- **-index**: A 0-based integer to access an element from an array.

<i>index</i>	0	1	2	3	4	5	6	7	8	9
<i>value</i>	12	49	-2	26	5	17	-6	84	72	3

element 0				element 4					element 9
-----------	--	--	--	-----------	--	--	--	--	-----------

# Array declaration

Format:

**type** [] **name** = new **type** [**length**] ;

–Example:

```
int[] numbers = new int[10];
```

<i>index</i>	<i>0</i>	<i>1</i>	<i>2</i>	<i>3</i>	<i>4</i>	<i>5</i>	<i>6</i>	<i>7</i>	<i>8</i>	<i>9</i>
<i>value</i>	0	0	0	0	0	0	0	0	0	0

# Array declaration, cont.

- The length can be any integer expression.

```
int x = 2 * 3 + 1;
```

```
int[] data = new int[x % 5 + 2];
```

- Each element initially gets a "zero-equivalent" value.

Type	Default value
int	0
double	0.0
boolean	false
String or other object	null (means, "no object")

# Accessing elements

**name**[**index**]                      *// access*  
**name**[**index**] = **value**;            *// modify*

– Example:

```
numbers[0] = 27;  
numbers[3] = -6;
```

```
System.out.println(numbers[0]);  
if (numbers[3] < 0) {  
    System.out.println("Element 3 is negative.");  
}
```

<i>index</i>	<i>0</i>	<i>1</i>	<i>2</i>	<i>3</i>	<i>4</i>	<i>5</i>	<i>6</i>	<i>7</i>	<i>8</i>	<i>9</i>
<i>value</i>	<b>27</b>	0	0	<b>-6</b>	0	0	0	0	0	0

# Arrays of other types

```
double[] results = new double[5];  
results[2] = 3.4;  
results[4] = -0.5;
```

<i>index</i>	<i>0</i>	<i>1</i>	<i>2</i>	<i>3</i>	<i>4</i>
<i>value</i>	0.0	0.0	<b>3.4</b>	0.0	<b>-0.5</b>

```
boolean[] tests = new boolean[6];  
tests[3] = true;
```

<i>index</i>	<i>0</i>	<i>1</i>	<i>2</i>	<i>3</i>	<i>4</i>	<i>5</i>
<i>value</i>	false	false	false	<b>true</b>	false	false

# Out-of-bounds

- Legal indexes: between **0** and the **array's length - 1**.
  - Reading or writing any index outside this range will throw an `ArrayIndexOutOfBoundsException`.

- Example:

```
int[] data = new int[10];  
System.out.println(data[0]);           // okay  
System.out.println(data[9]);           // okay  
System.out.println(data[-1]);          // exception  
System.out.println(data[10]);         // exception
```

<i>index</i>	<i>0</i>	<i>1</i>	<i>2</i>	<i>3</i>	<i>4</i>	<i>5</i>	<i>6</i>	<i>7</i>	<i>8</i>	<i>9</i>
<i>value</i>	0	0	0	0	0	0	0	0	0	0

# Accessing array elements

```
int[] numbers = new int[8];  
numbers[1] = 3;  
numbers[4] = 99;  
numbers[6] = 2;  
  
int x = numbers[1];  
numbers[x] = 42;  
numbers[numbers[6]] = 11; // use numbers[6] as index
```

*x*

3
---

	<i>index</i>	0	1	2	3	4	5	6	7
<i>numbers</i>	<i>value</i>	0	4	11	42	99	0	2	0

# Arrays and for loops

- It is common to use `for` loops to access array elements.

```
for (int i = 0; i < 8; i++) {  
    System.out.print(numbers[i] + " ");  
}  
System.out.println();    // output: 0 4 11 0 44 0 0 2
```

- Sometimes we assign each element a value in a loop.

```
for (int i = 0; i < 8; i++) {  
    numbers[i] = 2 * i;  
}
```

*index*    0    1    2    3    4    5    6    7

<i>value</i>	0	2	4	6	8	10	12	14
--------------	---	---	---	---	---	----	----	----

# The length field

- An array's `length` field stores its number of elements.

**name**.length

```
for (int i = 0; i < numbers.length; i++) {  
    System.out.print(numbers[i] + " ");  
}  
// output: 0 2 4 6 8 10 12 14
```

- It does not use parentheses like a String's `.length()`.

# Weather question

- Use an array to solve the weather problem:

How many days' temperatures? 7

Day 1's high temp: 45

Day 2's high temp: 44

Day 3's high temp: 39

Day 4's high temp: 48

Day 5's high temp: 37

Day 6's high temp: 46

Day 7's high temp: 53

Average temp = 44.6

4 days were above average.

# Weather answer

```
// Reads temperatures from the user, computes average and # days above average.
import java.util.*;

public class Weather {
    public static void main(String[] args) {
        Scanner console = new Scanner(System.in);
        System.out.print("How many days' temperatures? ");
        int days = console.nextInt();

        int[] temps = new int[days];           // array to store days' temperatures
        int sum = 0;

        for (int i = 0; i < days; i++) {      // read/store each day's temperature
            System.out.print("Day " + (i + 1) + "'s high temp: ");
            temps[i] = console.nextInt();
            sum += temps[i];
        }
        double average = (double) sum / days;

        int count = 0;                       // see if each day is above average
        for (int i = 0; i < days; i++) {
            if (temps[i] > average) {
                count++;
            }
        }

        // report results
        System.out.printf("Average temp = %.1f\n", average);
        System.out.println(count + " days above average");
    }
}
```
